Routing Protocol Security IT-Underground, Prague, 2007

Still a problem in 2007?

or

„An example of breaking OSPF“

```
^
| / _ | _ /
| \ _ / | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
+--> http://search.cpan.org/~gomor/ <----+
```

Who we are

■ Dror-John Roecher

- Security Consultant with a faible for enterprise networks and electronic gadgets.
- Based in Germany. Working for ERNW GmbH.
- Check this: www.ernw.de
- no cool nick

■ Patrice <GomoR> Auffret

- Security Engineer, Perl network developer
- Author of SinFP (an active and passive OS fingerprinting tool)
- Currently employed by a big service company based in France
- Check this: www.GomoR.org
- And also this:
www.GomoR.org/sinfp

```
^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

What we will be talking about...

- **Part1 - The (maybe not so) dull theory**
 - The „marketing blah“ – why the stuff we are talking about is important. (very brief!)
 - OSPF operations in some detail.
 - Some ways of breaking OSPF.
 - Mitigating OSPF (again brief)
- **Part2 - The BYOL audience-participation**
 - Show you our tools 😊
 - Attacking OSPF networks

```
^
| / _ | _ |
| \ _ / | \
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

Why this talk?

- Never found anything real good on „hacking“ OSPF – it was all theory and almost no hands-on.
- No tools available. Usually threats are only taken seriously when „tools“ are publicly available. So we need to change the lack of tools.
- Attacks on the infrastructure level are still not tapped to their full potential. Just remember yesterdays‘ „Digging into SNMP“ – another interesting „infrastructure level“ hacking technique.
- Plain old curiosity ,-))

```
^
| / _ | /
| \ _ | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

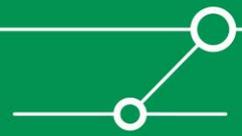

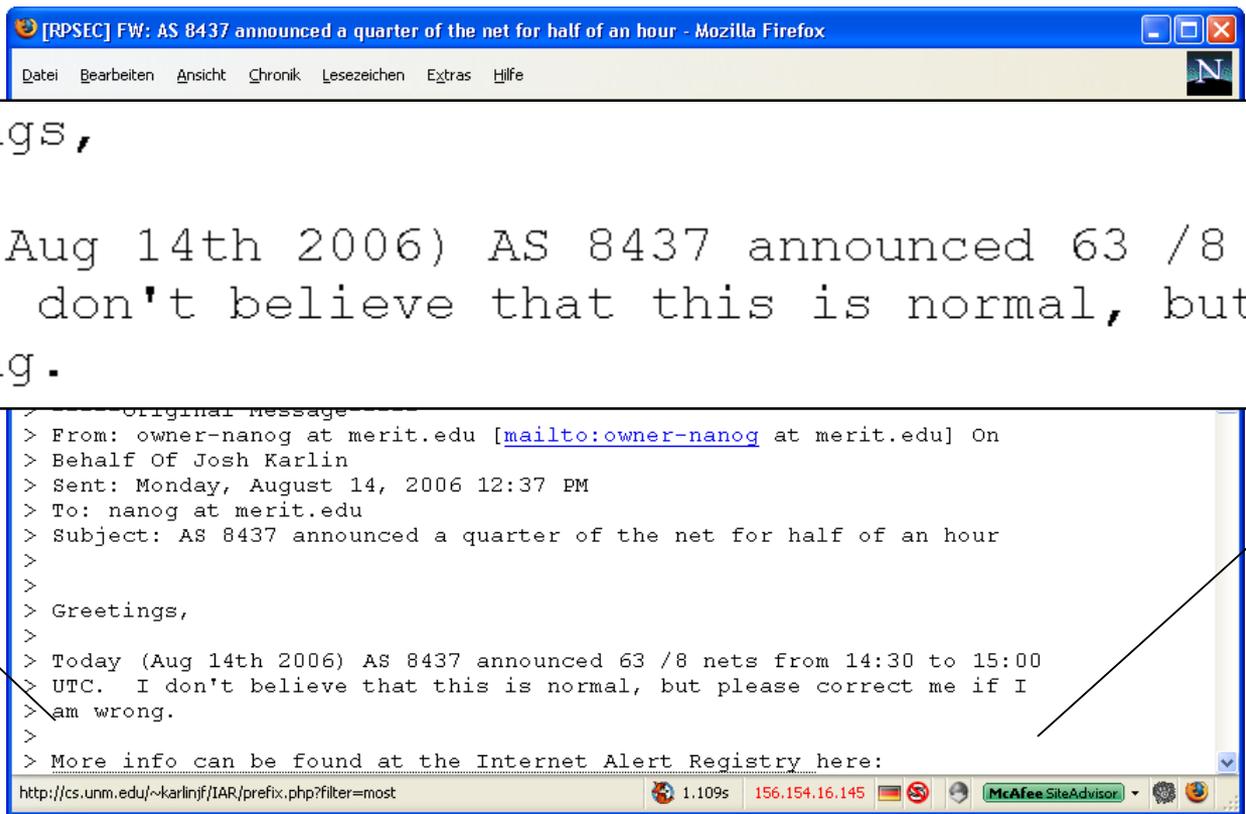

Brief History of „Routing Protocol Security“

- **Earliest known public discussion: RFC 789, Jan 1981.**
 - Faulty hardware caused faulty network control protocols which in „DoSed“ the ARPANet for a couple of hours...
- **A lot of discussion (with focus on BGP) ever since (just do a google search on „BGP Security“ and be overwhelmed)**
- **Many „add-ons“ [S-BGP, Secure BGP, etc] to BGP – but not much on other protocols.**
- **Structured effort in IETF „rpsec“ working group, but drafts are expired. They are really worth while reading – some guys put a lot of brain into these. Actually the best I have found on the topic so far!**

```
^
| / _/ | _/
| \ _/ | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

Scary... but fortunately only a „human error“

```
^
| / _ | _ |
| \ _ / | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

Routing Protocols in use...

- **BGP** runs the internet (besides DNS & caffeine).
- **OSFP** & **IS-IS** & **EIGRP** run enterprise networks.
- RIP is [mostly] dead.
- We will be talking (only) about OSPF (because that is what we will be doing in the BYOL and because it is in wide usage).

```
--  
^  
| /  _ |  _/  
| \  _/ |  \  
+--> Net::Frame <=> http://www.GomOR.org/ <--+  
Systems & Security Engineer |  
---[ zsh$ alias psed='perl -pe ' ]--- |  
http://search.cpan.org/~gomor/ <----+
```

Let's have a look at how OSPF works

OSPF „quick & dirty“

```
^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

OSPF „quick & dirty“

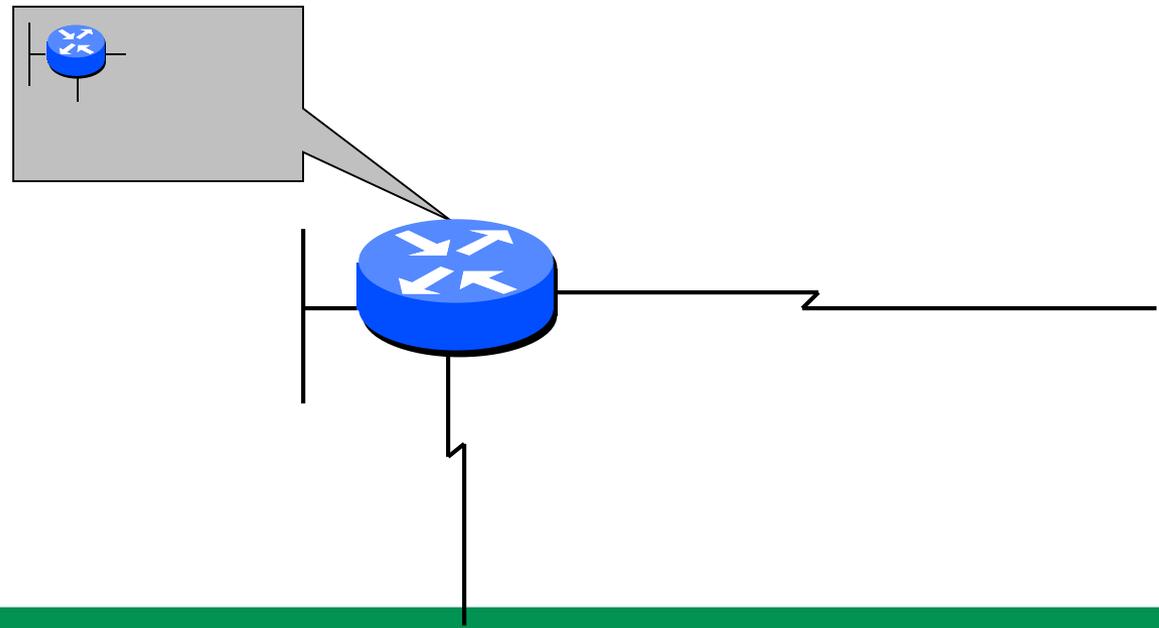

- 1. All OSPF Routers multicast periodic „Hello“ packets. If a „Hello“ is received from a different router (and if some additional requirements are met), than the routers form a „neighbor“-relationship.**
- 2. Certain neighborships are elevated to „adjacencies“. Adjacent routers synchronise their topology information through LSA-packets.**
- 3. The topology information is stored in a local database and used to graph the network.**
- 4. The graph is used to calculate the „shortest path tree“.**
- 5. From this tree routes to all networks are derived and installed into the routing-table.**

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

Link State Advertisements

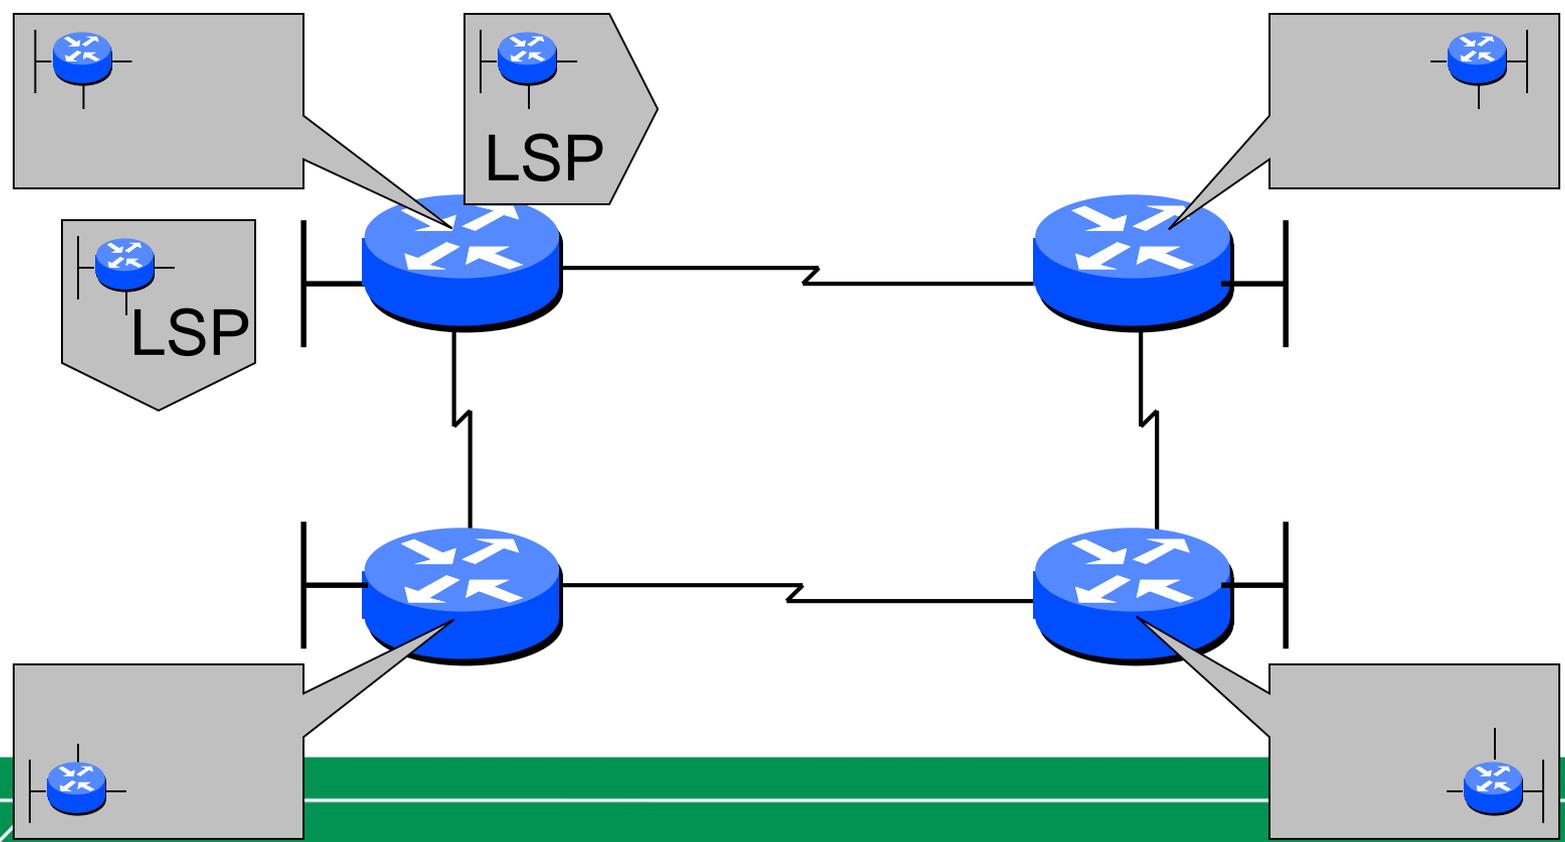

- Every Router advertises its own links.

```
^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

Link State Advertisements

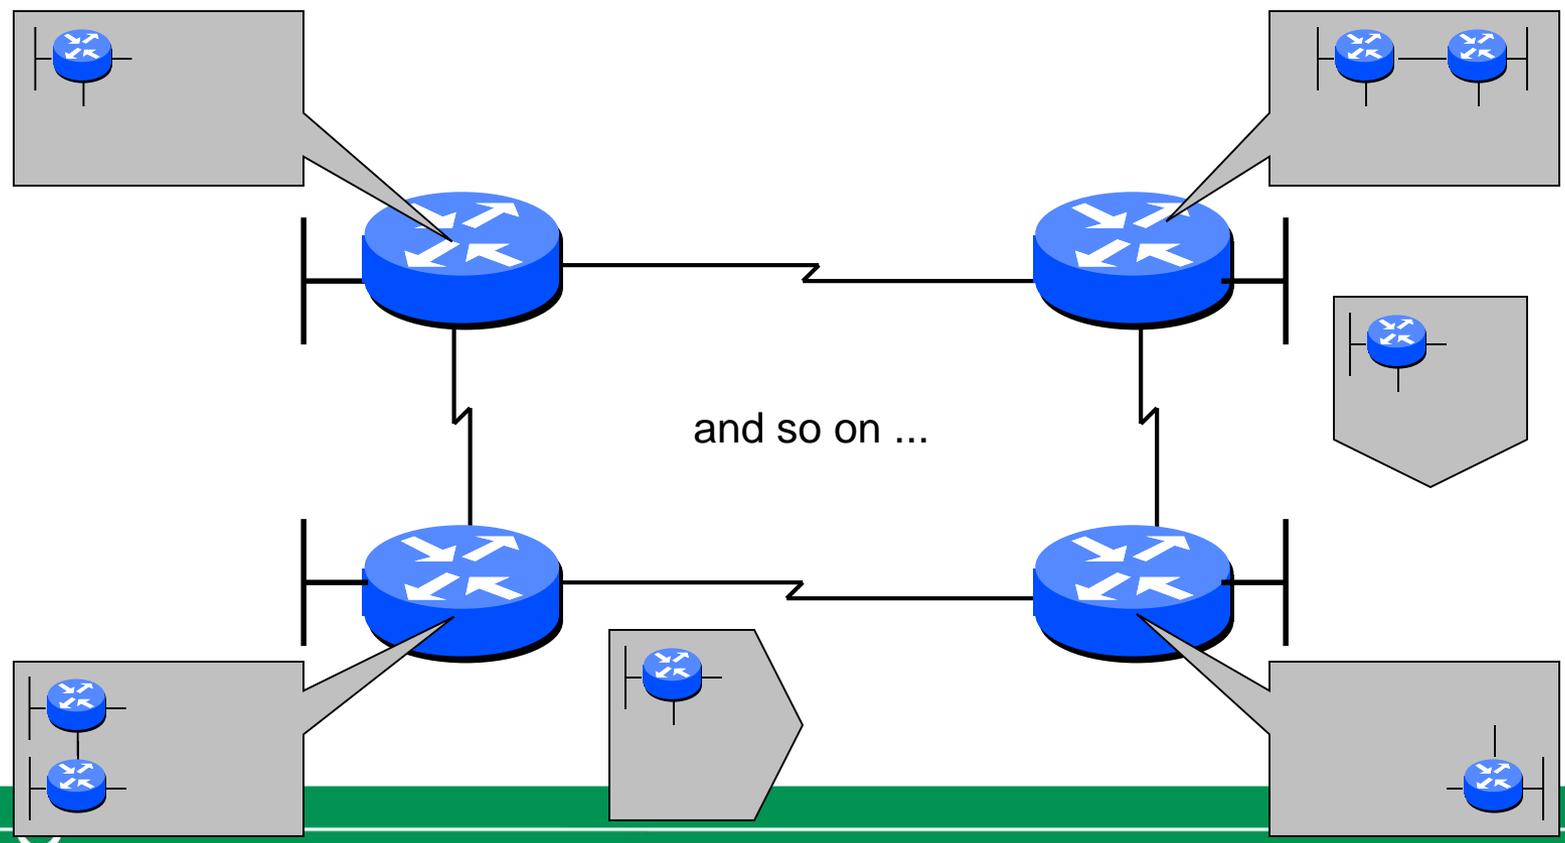

- These LSAs get flooded through the network

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

LSA and Flooding

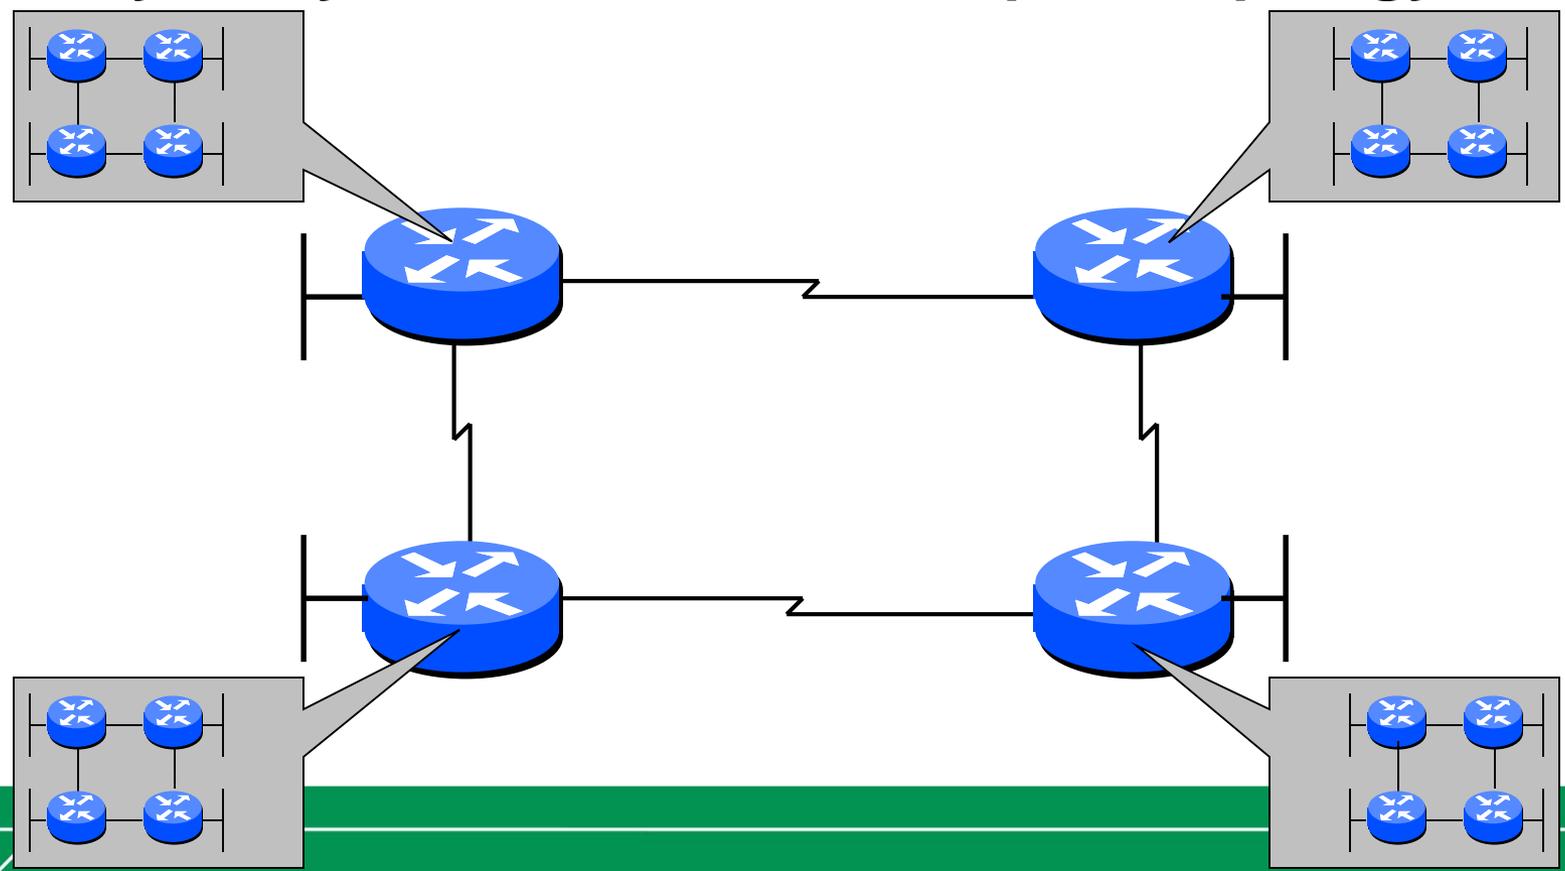

- Every router stores the received LSAs in its topology database

```
^
| / _ | _ |
| \ _ | \ _ |
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <---+
```

Full Topology

- Finally every router nows the complete topology

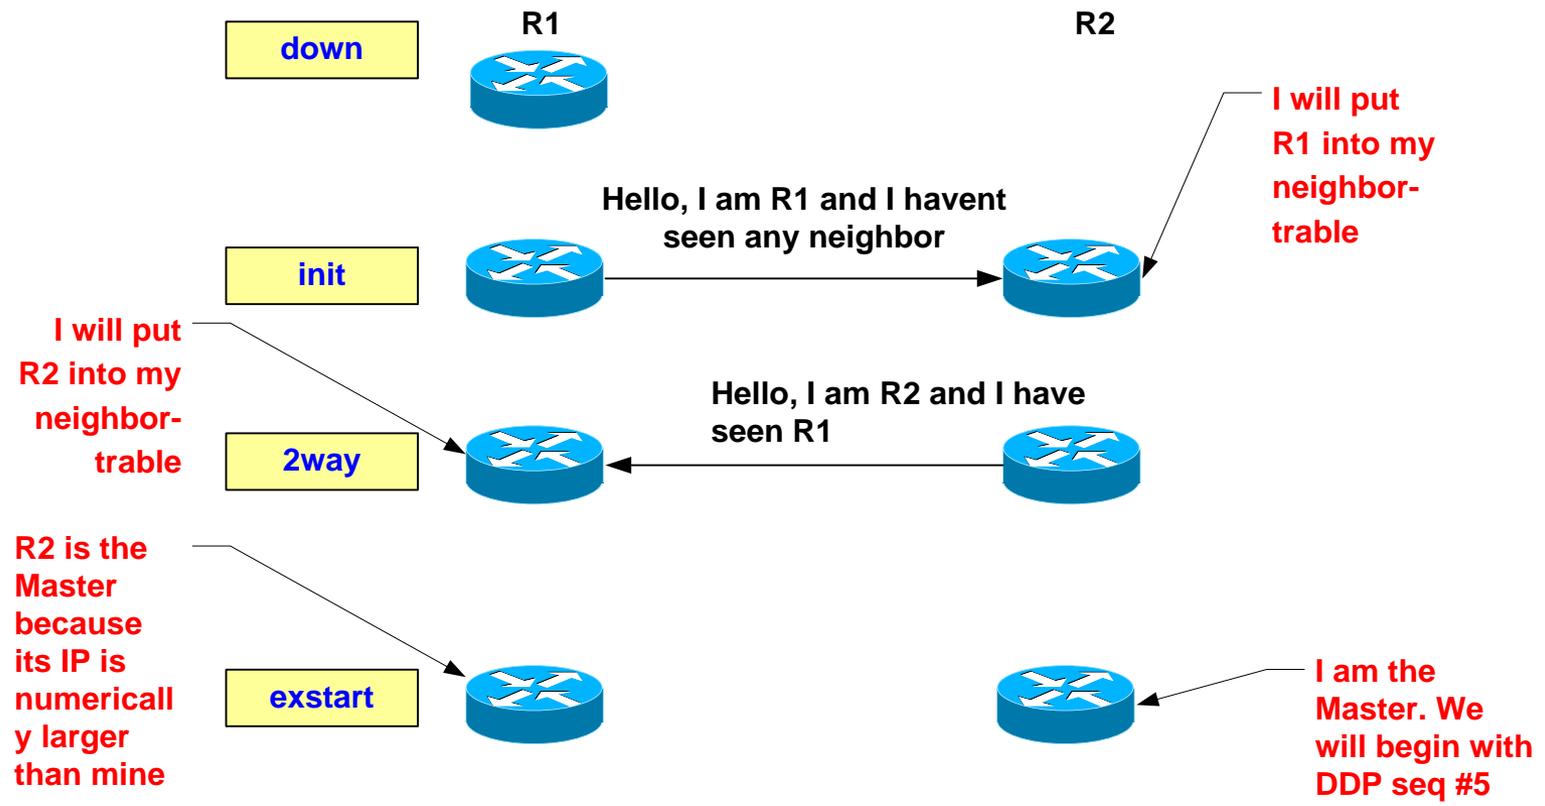

```

^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+

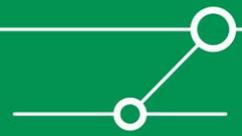

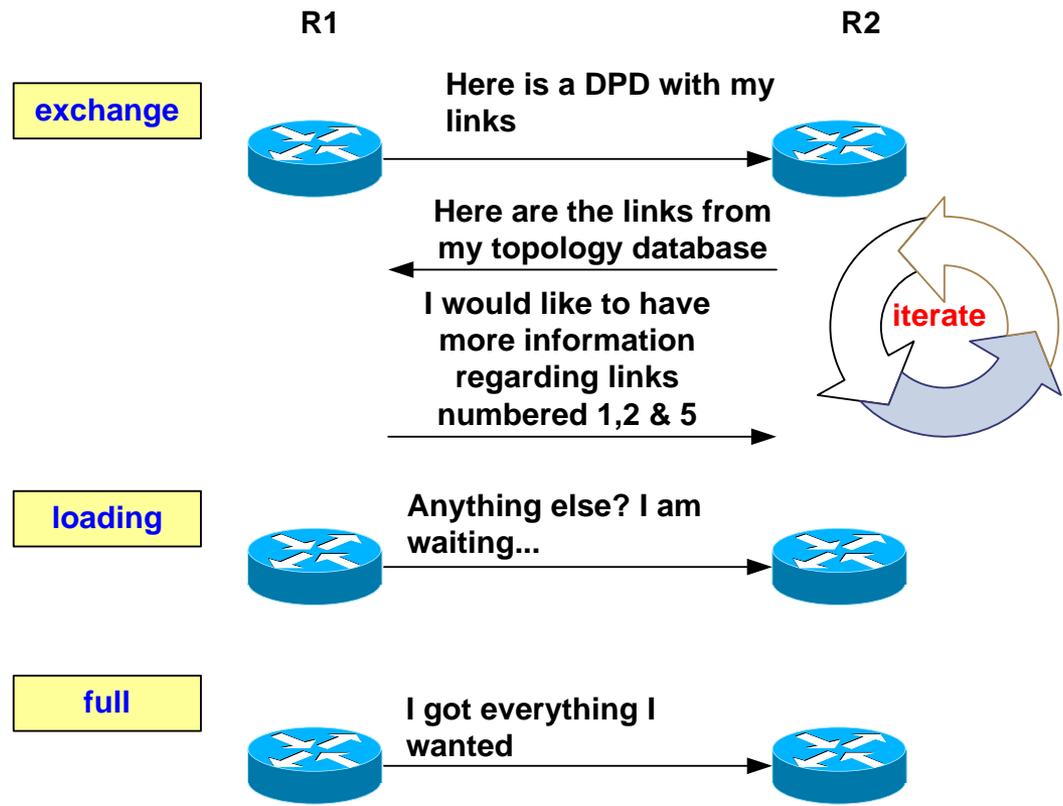

```

OSPF State Machine (1/2)

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

OSPF State Machine (2/2)

```
--  
^  
| / _ | _ |  
| \ _ | \ |  
+--> Net::Frame <=> http://www.GomoR.org/ <--+  
Systems & Security Engineer |  
---[ zsh$ alias psed='perl -pe ' ]--- |  
+--> http://search.cpan.org/~gomor/ <--+
```

OSPF Authentication

- **Per default OSPF has no authentication.**
- **Two different authentication-schemes exist, which can be used to increase security:**
 - Simple password authentication (that is plaintext passwords)
 - Message Digest authentication (md5 based)
- **Both are based on a „pre shared key“.**

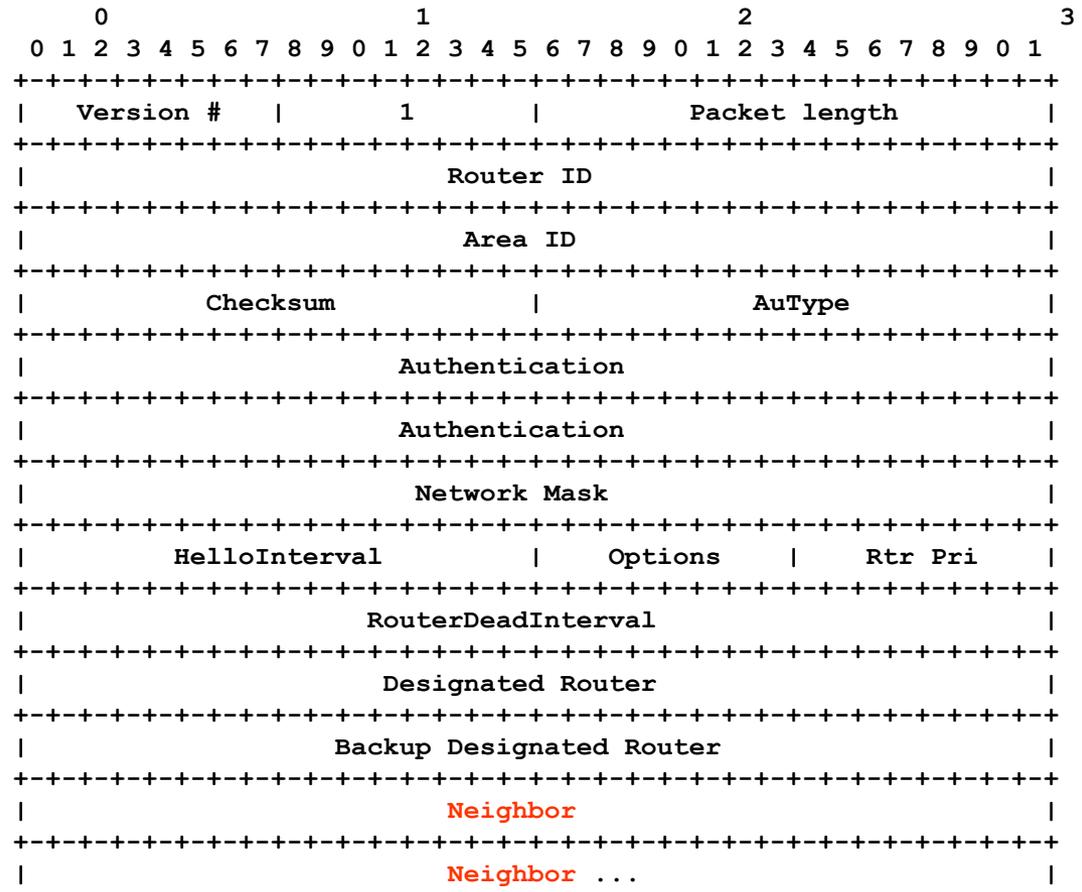

```

^
| / _ | _ /
| \ _ / | \
+--> Net::Frame <=> http://www.GomOR.org/ <-+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <---+

```

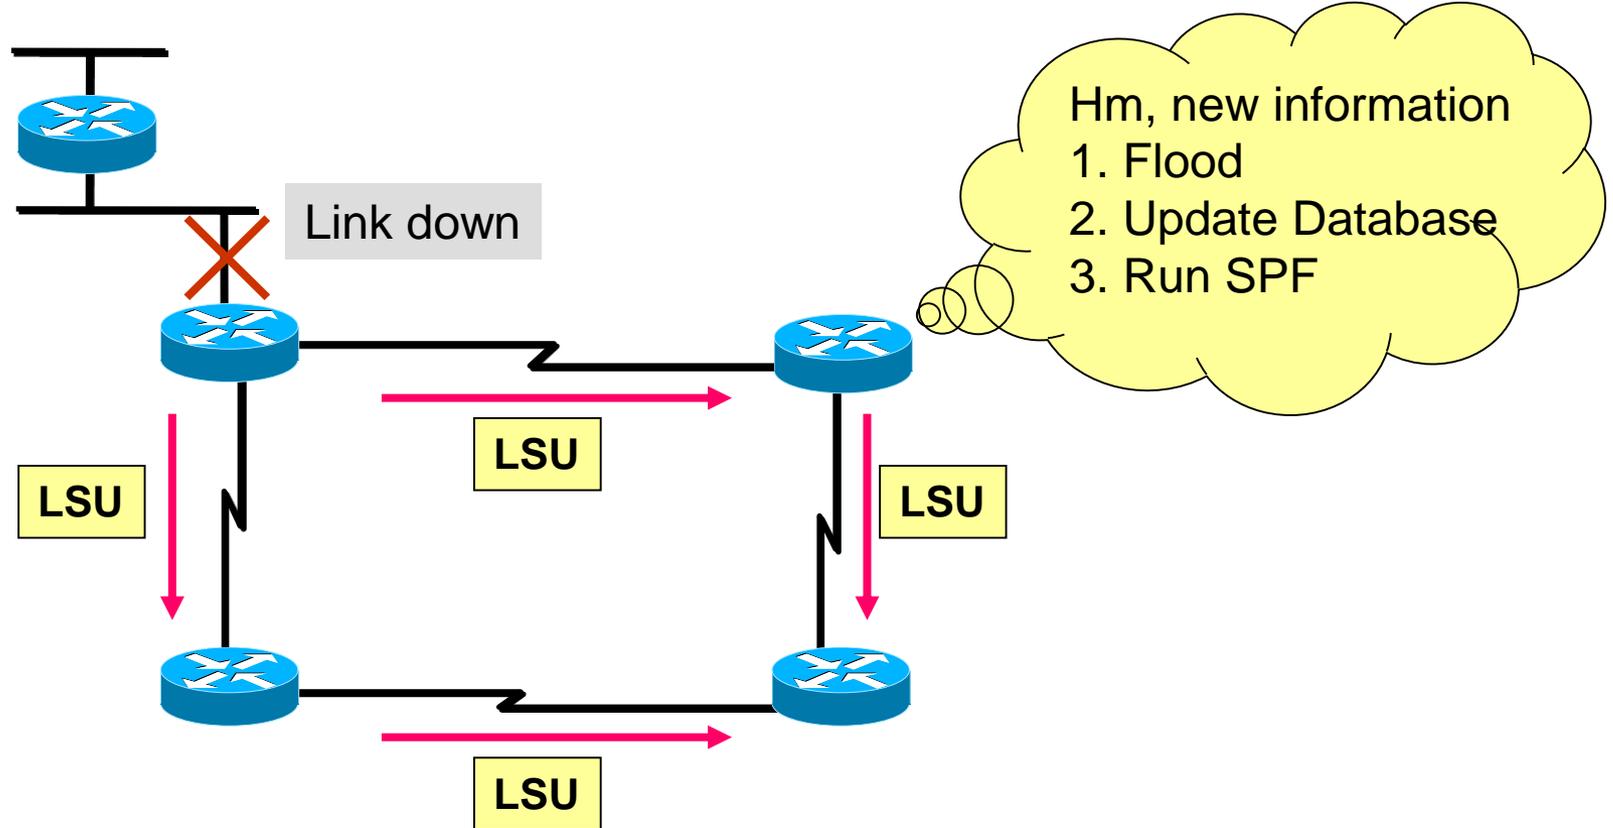

Hello Paket Format

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomOR.org/ <-->
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <-->
```

Flooding occurs when topology changes are noticed

```
^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
+--> http://search.cpan.org/~gomor/ <----+
```

OSPF Fightback mechanism

■ What is Fightback?

- Every LSA that is circulating with wrong information will be corrected by its owner. That is if an attacker spoofs an LSA from a different router with wrong information the original owner will correct it by sending „correct“ LSA.

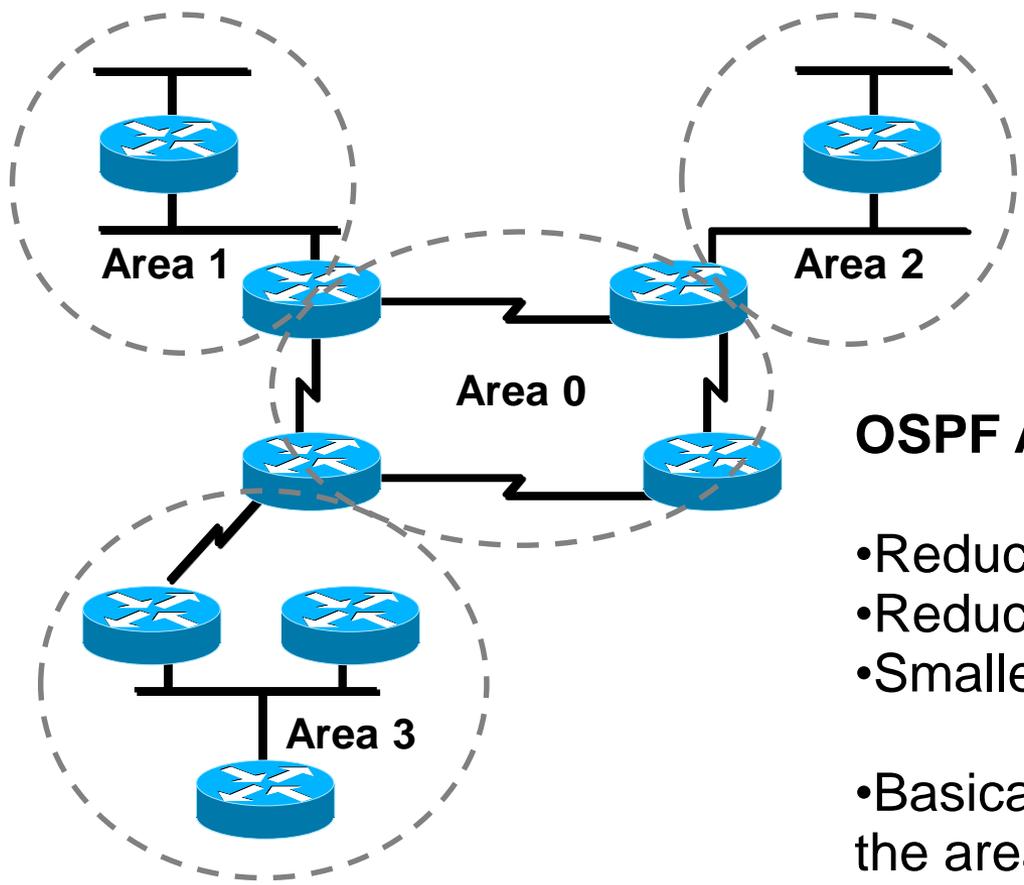

■ Common perception of fightback

- Fightback corrects most attacks (and therefor attacks on OSPF are not feasible)
- Many theoretical attacks will cause only a brief topology change and are therefor not feasible.
- Tell you something: **Theses perceptions are plain wrong** - I will show you later why ;-)

```
^
| / _ | /
| \ _ | \
+--> Net::Frame <=> http://www.GomOR.org/ <-+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <---+
```

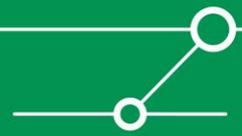

OSPF Areas

OSPF Area Konzept:

- Reduced Routing information,
- Reduced flooding of LSUs
- Smaller SPF tree – less CPU-cycles

- Basically: keep local changes local (to the area)

```
^
| / _ | _ /
| \ _ / | \
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

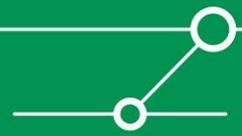

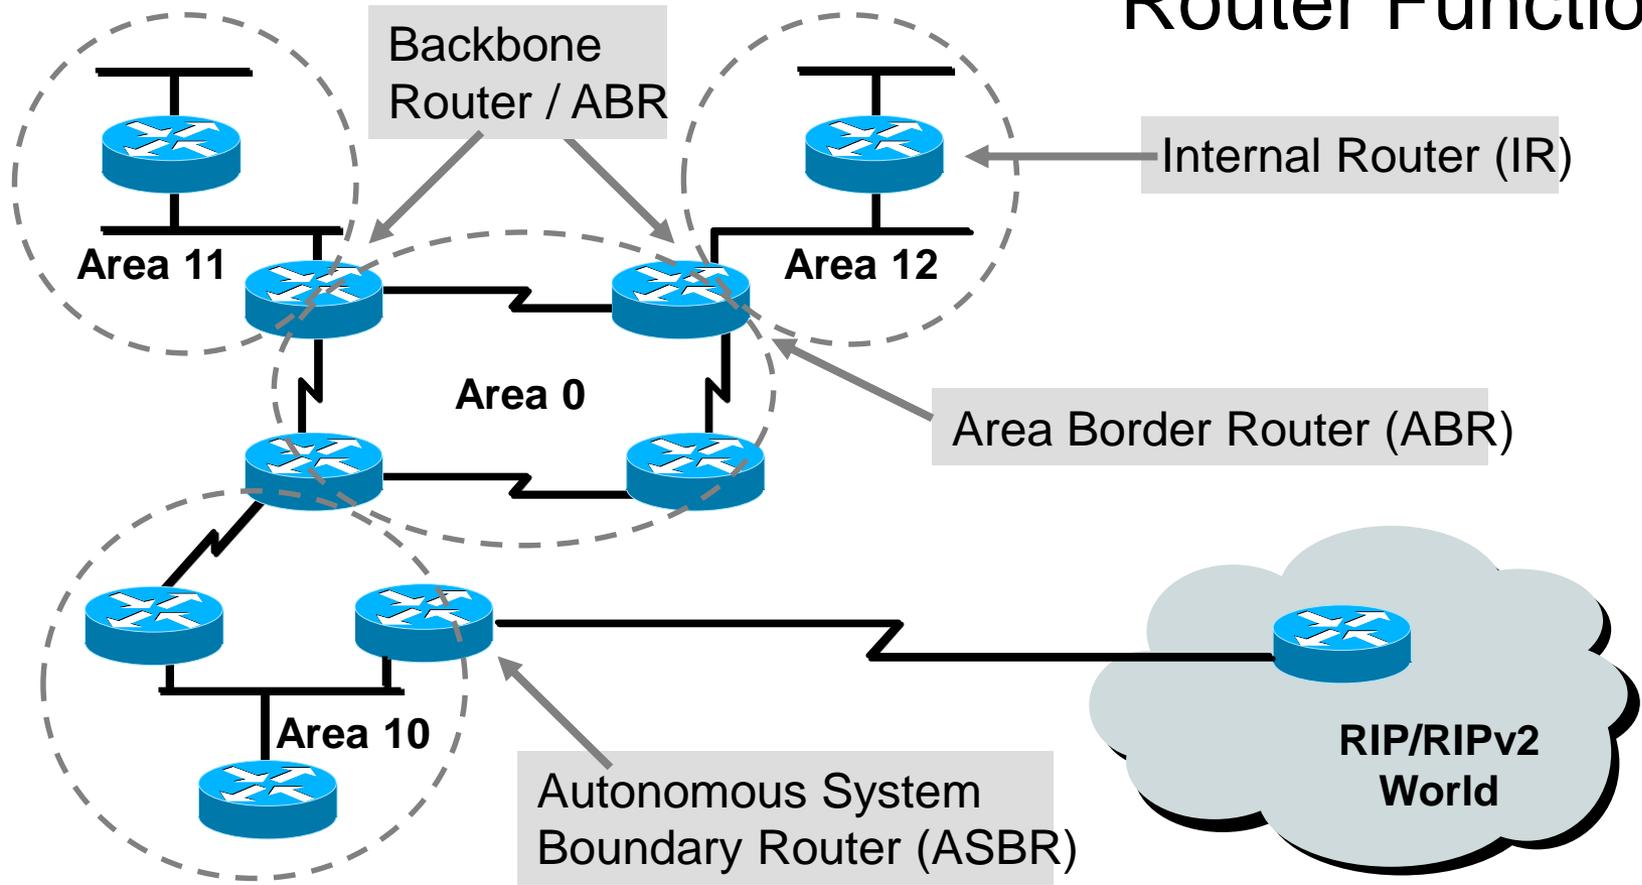

Some „rules“ on OSPF Areas

- Areas are identified by a 32-Bit identifier
- Area 0.0.0.0 (or simply Area 0) is always the Backbone Area.
- All other Areas must be directly connected to the Backbone Area.

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomOR.org/ <-+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <-->+
```

Router Functions

```
^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

Different Area Types – different information within

- **Normal Area**
 - All LSA Types are forwarded. (The Backbone Area always falls into this category)
- **Stubby Area**
 - No external LSAs are forwarded in stubby areas. Instead a default pointing to the ABR is inserted. Inter area routes are allowed.
- **Totally Stubby Area**
 - No external and no inter area routes – everything that is not local to the area is handled by a default-route.
- **Not So Stubby Area**
 - These area are basically stubby areas with external routes originating from a router within the area.

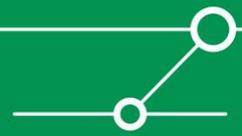

```

^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+

```

Different LSA for different information....

LSA-Type	who?	Content?
Type1:	everyone	Links
Type2:	DR	Network
Type3:	ABR	Network Summaries (interarea)
Type4:	ABR	Routes to the ASBR
Type5:	ASBR	External Routes
Type7:	ASBR	NSSA External Routes (Type7-LSAs are converted by ABRs to Type5-LSAs).

```
^
| / _ | _ /
| \ _ / | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

LSA Types

- **Router Links (Type1-LSA)**
- **Every Router** sends information about connected links as **Type1-LSA**.
- **Network Links (Type2-LSA)**
- **DR** send Network Link LSAs as **Type2-LSAs**, these include information about the network (network address, netmask, connected router).
- **Network-Summary (Type3-LSA)**
- **Type3-LSAs** include informationen for networks in other areas and are generated by **ABRs**. (Type3-LSAs are not include in SPF calculation).

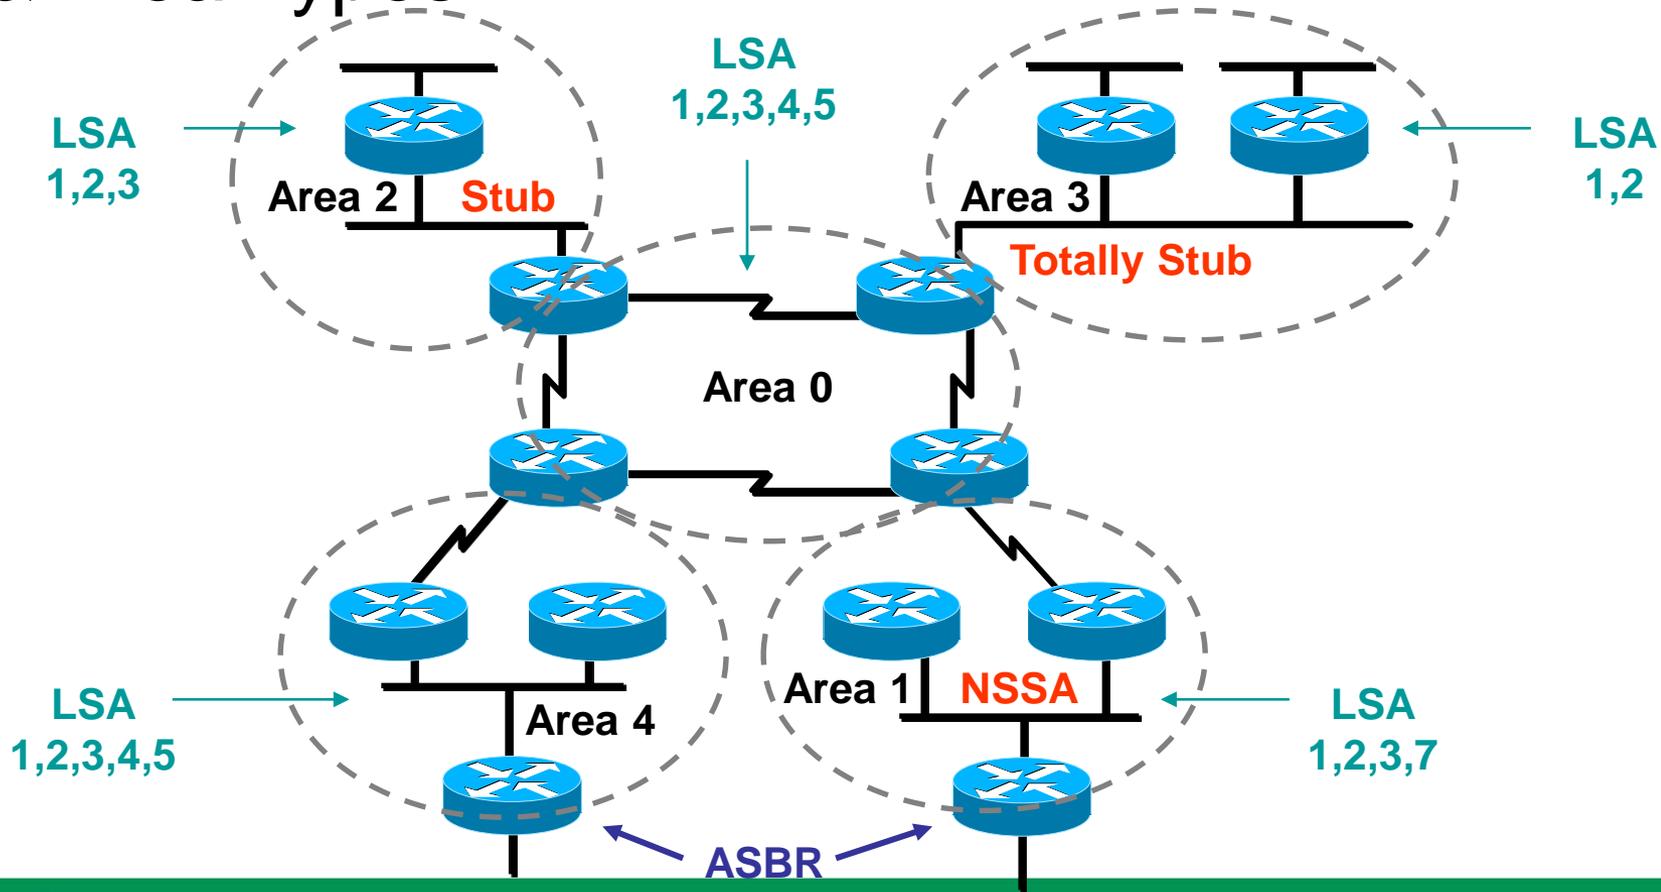

```
^
| / _ | /
| \ _ | \
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <-->
```

LSA Types

- **ASBR Summary (Type4-LSA)**
- **LSA Type4** are generated by **ABRs** and include routes to the ASBRs).
- **ASBR External LSA (Type5-LSA,Type7-LSA)**
- **ASBRs** send ASBR External LSAs (**Type5-LSA**), including information about networks outside the OSPF AS or a default route to outside the OSPF AS.
- If these Type-5 LSAs are sourced by an ASBR of a NSS, it is send as a **Type7-LSA**. Type7-LSAs are changed to **Type5-LSAs** by the ABR of the NSSA.

LSAs & Area Types

sh ip route - standard area

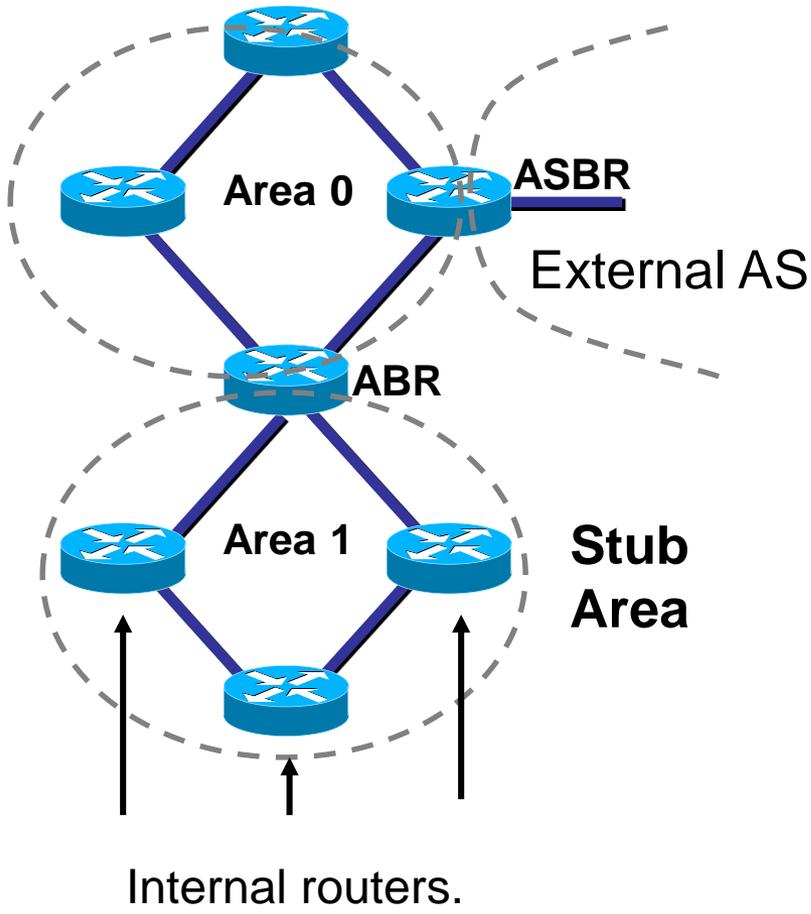

```
RouterA#sh ip route
Codes:  C - connected, O - OSPF, IA - OSPF inter area
        E1 - OSPF external type 1, E2 - OSPF external type 2,
        * - candidate default

Gateway of last resort is not set

      203.250.15.0 255.255.255.252 is subnetted, 1 subnets
C       203.250.15.0 is directly connected, Serial0
O IA    203.250.14.0 [110/74] via 203.250.15.1, 00:06:31, Serial0
        128.213.0.0 is variably subnetted, 2 subnets, 2 masks
O E2    128.213.64.0 255.255.192.0
        [110/10] via 203.250.15.1, 00:00:29, Serial0
O IA    128.213.63.0 255.255.255.252
        [110/84] via 203.250.15.1, 00:03:57, Serial0
        131.108.0.0 255.255.255.240 is subnetted, 1 subnets
O       131.108.79.208 [110/74] via 203.250.15.1, 00:00:10, Serial0

                        +--> http://search.cpan.org/~gomor/ <----+
```

OSPF Attack Vectors...

That is what we will talk about today :-)

■ Classification of attack-vectors:

- Attacks which originate from the outside of the OSPF network
 - Prerequisite: Attacker is able to send unicast OSPF-packets to an internal OSPF router. This should not be possible, because OSPF packets should not be allowed to enter the network.
- Attacks which originate from the inside of the OSPF network
 - **Device Compromise:** Attacker has administrative access (console or ssh) to an OSPF-router.
 - **Link Compromise:** Attacker has access to a network-link, where OSPF is being spoken by one or more connected routers.
- Attacks through „broken“ implementations: BOs in ospfd etc. – not in scope for today's talk, even though they may have a huge impact on overall security.

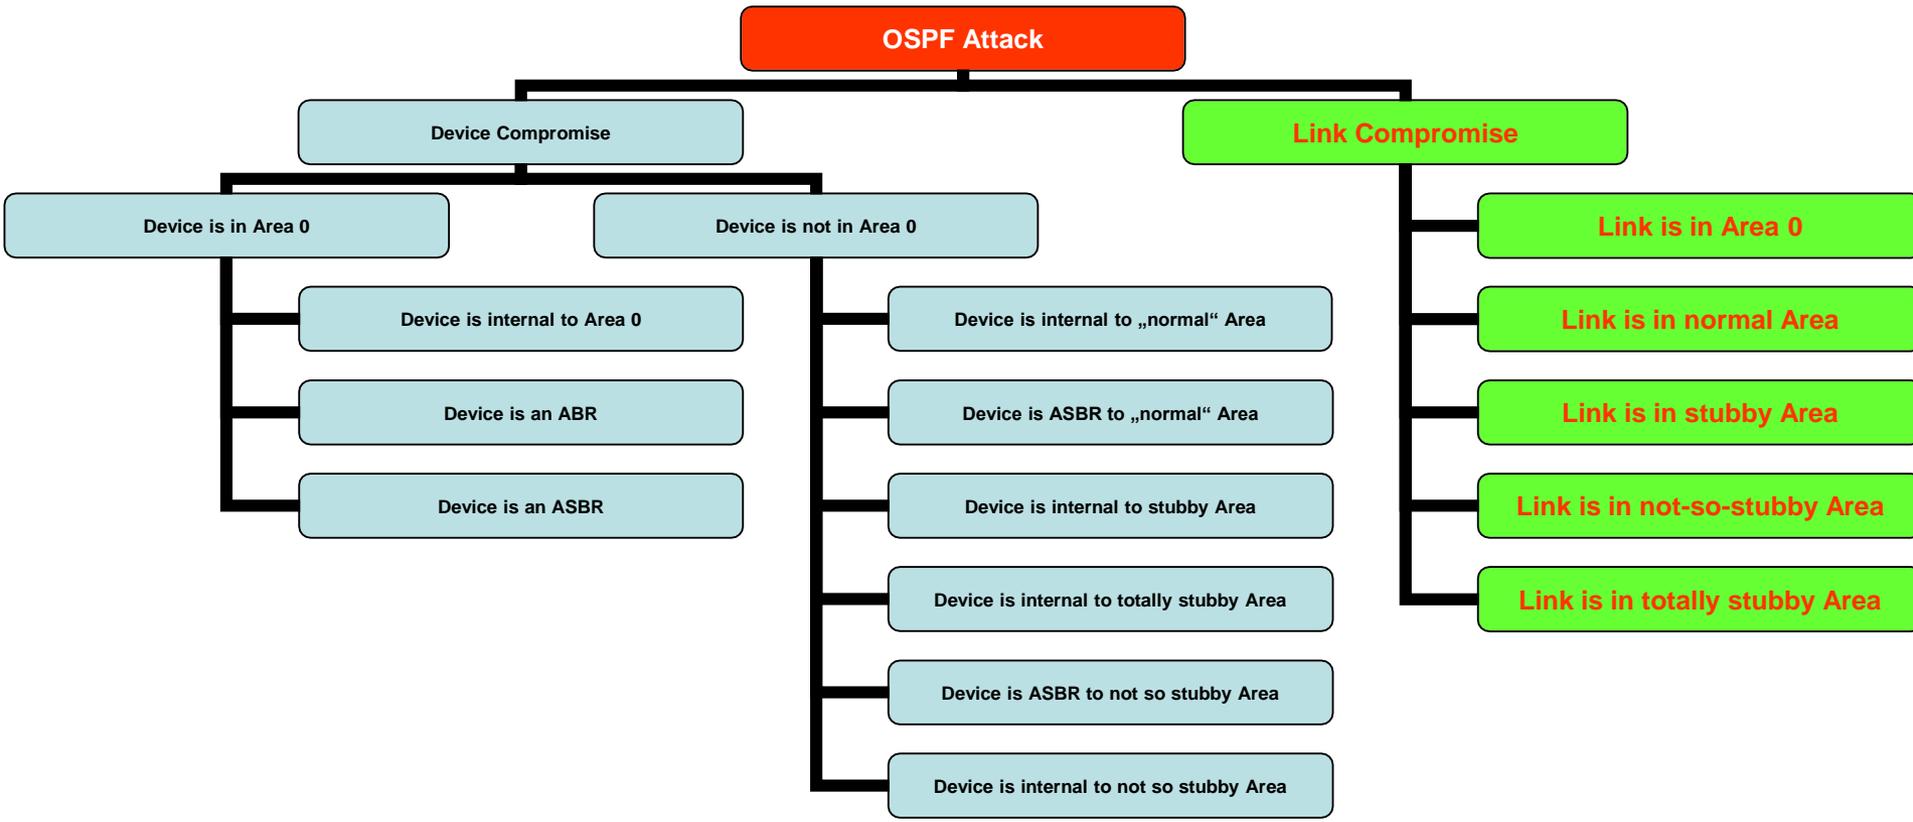

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

Link Compromise

- **Link is in Area 0**
- **Link is not in Area 0**
 - Link is in „normal“ Area
 - Link is in „stubby“ Area
 - Link is in „not so stubby“ Area
 - Link it in „totally stubby“ Area

The Attack Vectors as a graph

```
^
| / _ | _ |
| \ _ / | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
+--> http://search.cpan.org/~gomor/ <----+
```

Some Threats through Device Compromise

- **We will not go into depth here (mostly for time-reasons and because threats are somewhat obvious).**
- **Some possible threats:**
 - DoS: Dropping of routes
 - DoS: (Partial) Disabling of OSPF
 - DoS: Addition of „bogus“ routes via loopback interfaces (e.g. with /32 mask to have a „longest match“)
 - DoS: Creating Routing loops (which adds congestion besides DoS)
- **These are not very interesting, because any change to OSPF will affect the local routing table, too and the interesting attacks avoid just that.**

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <---+
```

Threats through Link Compromise

■ Denial of Service:

- Blackhole: Traffic is directed to a router which cannot handle the load.
- Starvation: Traffic is forwarded to a part of the network, that can not deliver it.
- Delay: Traffic is routed via a suboptimal path.
- Loop: Traffic is forwarded along a looping path.
- Partition: Some part of the network believes it is partitioned from the rest, when in fact it is not.
- Churn: Forwarding on the network changes rapidly, resulting in large variations of data-delivery patterns (impacting congestion control mechanisms).
- Instability: OSPF itself becomes unstable so that global convergence is never achieved.
- Overload: OSPF messages themselves become a significant part of the network traffic.
- Resource Exhaustion: OSPF messages cause exhaustion of router resources (queues, memory, cpu).

■ Man in the Middle

- Eavesdropping: Carefully crafted insertion of routing information may lead to rerouting through attacker which may put the attacker in the packet-path. These are quite difficult to accomplish. But this is (imho) the most interesting attack scenario.

```
^
| / _ | /
| \ _ | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

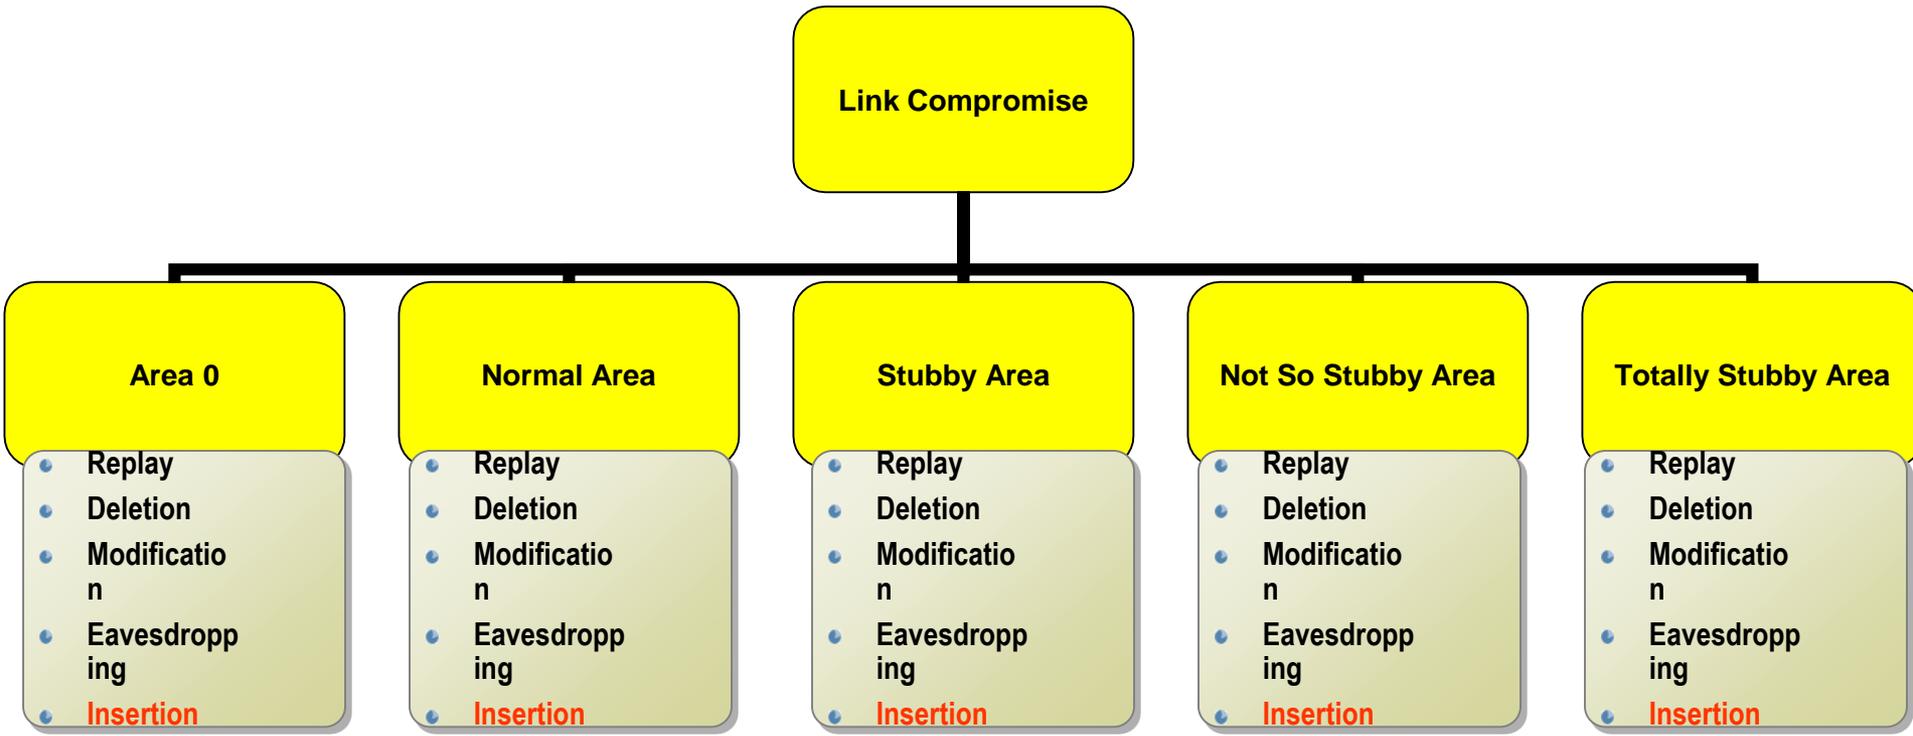

Attacks on „Link Compromise“ fall into one of these classes

- **Message Replay**
- **Message Insertion (that will be the focus today)**
- **Message Deletion (usually detectable by the sender)**
- **Message Modification**
- **Message Eavesdropping (almost always needed to gain some knowledge about how OSPF is set up)**

```
^
| / _ | /
| \ _ | \
+--> Net::Frame <=> http://www.GomOR.org/ <-+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <---+
```

Link Compromise

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <---+
```

Abetting Factors – Link Compromise

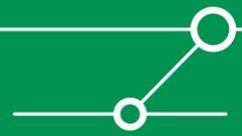

- **OSPF Routers on Broadcast, NBMA, PtMP and Virtual Links accept Unicast packets (Section 8.1 in RFC 2328). Therefor many attacks for link-compromise work also „from remote“, as long as the attacker is able to send IP-Protocol-89 packets to a legitimate OSPF router.**
- **Usually same key used on all links (if any at all).**
- **Tools for breaking OSPF-MD5-keys exist (e.g. Cain & Abel)**

```
--  
^  
| /  _ |  _/  
| \  _/ |  \  
+--> Net::Frame <=> http://www.GomOR.org/ <--+  
Systems & Security Engineer |  
---[ zsh$ alias psed='perl -pe ' ]--- |  
http://search.cpan.org/~gomor/ <----+
```

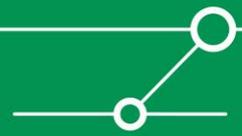

Attack Classification - **Message Insertion**

```
^
| / _ | _ |
| \ _ / | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <---+
```

Categories of Attacks – Message Insertion (1/2)

- **Setting up phanthom routers (routers that dont exist)**
 - Simple „hello“ suffices to get into neighbor-tables. But that should have no impact – just a „gimmick“
- **Spoofing messages from existing routers**
 - Send „hellos“ with on a link where the router acutally isnt located (not sure if OSPF fightback should come into place).
 - Send „hellos“ on a link where the router is located
 - Send spoofed LSAs (here the OSPF fightback mechanism should come into place) – which can be leveraged for DoS by taking advantage of timer-mechnisms in OSPF.

```
^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomOR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

Categories of Attacks – Message Insertion (2/2)

- **Adding a „real“ router – rerouting to traffic**
 - In the Backbone Area
 - Inject Type 1,2,3,5 LSAs
 - In a normal Area
 - Inject Type 1,2,3,5 LSAs
 - In a stubby Area
 - Inject Type 1,2,3 LSAs
 - In a totally Stubby Area
 - Inject Type 1,2 LSAs
 - In a NSSA
 - Inject Type 1,2,7 LSAs

```
^
| / _ | _ |
| \ _ / | \
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

When adding a „real“ router...

- **Message Insertion aimed at manipulating routing information:**
 - Add „new“ networks (e.g. 194.77.14.0/24) as „internal“ to an Area
 - Add existing networks used in a different Area
 - Add default routes
 - Either as ABR
 - Or as ASBR
 - Add new Areas – with new networks
 - Add new Areas – with networks already used somewhere else in the AS
- **Possibilities depend on where the compromised link is located.**

```
^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

When sending spoofed LSAs...

- **OSPF „Fightback“ should kick in, but...**
 - Using periodic injection of spoofed LSAs will exploit that there is a MinLSInterval timer (default 5 seconds). The legitimate owner of the LSA will honor that interval, an attacker will not. Resulting in permanent or semi-permanent changes to the topology
 - And the legitimate owner may even help in flooding the spoofed LSA...
 - The spoofed LSA has a higher squence number.
 - A copy of the LSA is already present on the original router in the LSDB and this copy was installed and not received through flooding.
 - **Effect: The malicious LSA will be first flooded by the legitimate owner and then checked for „correctnes“.**
 - After the error is uncovered, the legitimate router will try to correct. Try, because of MinLSInterval (dont send the same LSA faster than MinLSInterval) – but in the meantime a new spoofed LSA might arrive, which will be flooded immediately...
 - Using Message-Modification or Message-Deletion an attacker may prevent the legitimate owner of ever receiving the spoofed LSA. Then Fightback will never occur.

```
^
| / _ | _ |
| \ _ | _ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        http://search.cpan.org/~gomor/ <----+
```

There are more ways to break OSPF

- But we havent explored them all yet... more work to do.
- We have limited time for the session – so we had to choose which one to show.
- Some need very deep OSPF knowledge – again time constraints prevent talking about these.
- Some depend on „special“ circumstances / setups – we have neglected these so far.
- If you feel like you could contribute and if you would like to contribute – contact us.
- If you want to know more – contact us.

```
^
| / _ | _ |
| \ _ | \ |
+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <--+
```

And at the end a few words on the other protocols...

- **RIP** makes it even easier than OSPF to manipulate the routing domain – my advice: just don't use it.
- **IS-IS** should be as difficult to hack as OSPF – but there is even less on IS-IS security than on OSPF security. Now that is a topic where one could earn one's first wings... and sites running IS-IS are usually very large.
- **EIGRP** is proprietary Cisco stuff – not too much known on that (FX released „irpas“ some years ago – but as to my knowledge no one followed the lead and expanded on his work)
- **BGP** seems to get the most attention – because it „runs the internet“ and hacking that would have a real global (economic) impact.

```

+--> Net::Frame <=> http://www.GomoR.org/ <--+
                        Systems & Security Engineer |
                        ---[ zsh$ alias psed='perl -pe ' ]--- |
                        +--> http://search.cpan.org/~gomor/ <----+
```

Mitigating attacks on OSPF

■ Preventive:

- Use md5-authentication with strong passwords
- Change passwords periodically
- Disable OSPF on access-links (dont expose your passwords to clients!)
- Instead of „passive interface“ consider using „redistribution“ of connected access-networks (dont accept OSPF messages on these interfaces – not sure about this one, needs validation and has impact on routing!)
- Strict ingress filtering (but make sure not to break your routing)
 - From outside, of course never ever accept OSPF (ip protocol 89)
 - From access-networks, never ever accept OSPF (ip protocol 89)
 - Multicast Filtering (224.0.0.5 & 224.0.0.6) may come in handy, too.
- Use Summarization
 - This may keep attacks local to an area (not sure, needs validation!)

■ Detective:

- Monitor OSPF neighbor changes (unexpected new neighbor is usually not something you want to see on your network)
- Monitor routing-changes (changes not related to a link/hardware failure should make you suspicious)
- Anomaly-based IDS could be taught to detect unnormal OSPF behaviour - need to validate.

```

Prerequisites for BYOL

- **Technical**
 - A networked Laptop with VMWare Workstation or Server installed
 - Our prepared VMWare-Image
- **Knowledge & Experience**
 - Some knowledge of Linux & Perl
 - Some experience with Cisco IOS
- And **please follow the instructions**, the lab is quite complex and we want to avoid total chaos.
